1 - Spend (base M-of-N + delegated authorizations)

The wallet pays out. The spending script enforces its base M-of-N signature floor and forwards every other check to the withdrawal scripts named in the config UTxO; the single spend redeemer asserts their conjunction.

Notes:

- wallet_addr: payment is wallet_hash, staking any. Wallet UTxOs carry no datum; they may hold ada and arbitrary native assets.
- wallet_hash = hash(spend_validator(config_policy)): the spending script is parameterized only by the config beacon policy, so all wallet UTxOs share one address and the config can change without redeploying.
- base M-of-N floor (L1): the config UTxO is read as a **reference input**, and the spend requires at least threshold of members present in extra_signatories. A member may itself be a script credential, so the floor can be another multisig, a DAO, and so on.
- delegated authorizations (L1): every Credential in config.withdrawals is a withdraw-0 staking script that must run in this transaction. The single spend redeemer asserts the conjunction — the M-of-N floor **and** all delegated checks — so no restriction can be silently omitted.
- the delegated scripts are the extension point: spending limits, time locks, recipient allow-lists, oracle attestations, ... each is an independent withdrawal script observed here, none known to the spending script.
- composability: the spend asserts only its own inputs, the referenced config, and that the required withdrawals ran — never the total input or output counts, nor unrelated UTxOs.

2 - Update config (self-governance)

The wallet rewrites its own restrictions — *members*, *threshold*, or the list of delegated withdrawal Credentials — in place. The config UTxO is the settings protocol’s beacon-authenticated UTxO, so consumers never redeploy.
